

EPDS_Web

Feb 13, 2016

Mohammed.hussaini

Executive Summary

Issues Overview

On Feb 13, 2016, a source code review was performed over the EPDS_Web code base. 449 files, 276 LOC (Executable) were scanned and reviewed for defects that could lead to potential security vulnerabilities. A total of 19 reviewed findings were uncovered during the analysis.

Issues by Fortify Priority Order

Critical	10
High	9

Recommendations and Conclusions

The Issues Category section provides Fortify recommendations for addressing issues at a generic level. The recommendations for specific fixes can be extrapolated from those generic recommendations by the development group.

The scan found 19 issues.

Vulnerability Examples by Category

Category: Privacy Violation: Autocomplete (9 Issues)

Explanation:

With autocompletion enabled, some browsers retain user input across sessions, which could allow someone using the computer after the initial user to see information previously submitted.

Recommendations:

Explicitly disable autocompletion on forms or sensitive inputs. By disabling autocompletion, information previously entered will not be presented back to the user as they type. It will also disable the "remember my password" functionality of most major browsers.

Example 1: In an HTML form, disable autocompletion for all input fields by explicitly setting the value of the autocomplete attribute to off on the form tag.

```
<form method="post" autocomplete="off">
Address: <input name="address" />
Password: <input name="password" type="password" />
</form>
```

Example 2: Alternatively, disable autocompletion for specific input fields by explicitly setting the value of the autocomplete attribute to off on the corresponding tags.

```
<form method="post">
Address: <input name="address" />
Password: <input name="password" type="password" autocomplete="off"/>
</form>
```

Note that the default value of the autocomplete attributed is on. Therefore do not omit the attribute when dealing with sensitive inputs.

login-page.html, line 28 (Privacy Violation: Autocomplete)

Fortify Priority:	High	Folder	High
Kingdom:	Security Features		
Abstract:	The form in login-page.html uses autocompletion on line 28, which allows some browsers to retain sensitive information in their history.		
Sink:	login-page.html:28 null()		
26	</div>		
27	<div class="form-group">		
28	<input type="password" name="userPwd" class="form-control"		
29	data-ng-model="credentials.userPwd" placeholder="Password"		

30	required />
----	-------------

Category: Password Management: Insecure Submission (8 Issues)

**Explanation:**

By convention, the parameters associated with an HTTP GET request are not treated as sensitive data, so web servers log them, proxies cache them, and web browsers do not make an effort to conceal them. Sending a password or other sensitive data as part of an HTTP GET will likely cause the data to be mishandled and potentially revealed to an attacker.

Example 1: In the example below, new user password is submitted via an HTTP GET request.

```
<form method="get">
Name of new user: <input type="text" name="username">
Password for new user: <input type="password" name="user_passwd">
<input type="submit" name="action" value="Create User">
</form>
```

Also, note that the default value of the method attributed is GET, thus omitting the attribute results in the same outcome.

Recommendations:

Avoid sending sensitive data, such as passwords, via an HTTP GET request. Sensitive data should travel from the browser to the server using HTTP POST, not HTTP GET.

Example 2: In the example below, new user password is submitted via an HTTP POST request.

```
<form method="post">
Name of new user: <input type="text" name="username">
Password for new user: <input type="password" name="user_passwd">
<input type="submit" name="action" value="Create User">
</form>
```

HTML5 adds the ability to specify the formmethod attribute as part of the submit and image input tags, and the value of this attribute overrides the value of the method attribute of the corresponding form tag.

Example 3: In the example below, new user password is also submitted via an HTTP POST request, which is specified by the formmethod attribute of the submit input tag.

```
<form method="get">
Name of new user: <input type="text" name="username">
Password for new user: <input type="password" name="user_passwd">
<input type="submit" name="action" value="Create User" formmethod="post">
</form>
```

However, be aware that if the value of the formmethod attribute is set to get, the form will be submitted via an HTTP GET request no matter what the method attribute of the corresponding form tag specifies.

Avoid sending sensitive data via an HTTP redirect, because it causes the user's web browser to issue an HTTP GET request. The application should either store the sensitive data in a session object so that it does not need to be transmitted back to the browser or simply discard the data and ask the user to enter it again. Other options, such as embedding the sensitive data in a web page that automatically posts its data, are also problematic because the web page may be cached by a proxy or by the web browser. As is often the case, security may need to trump usability in this instance.

nonVendorPasswordUpdate.html, line 14 (Password Management: Insecure Submission)

Fortify Priority:	Critical	Folder	Critical
Kingdom:	Security Features		
Abstract:	The form in nonVendorPasswordUpdate.html submits a password as part of an HTTP GET request on line 14, which will cause the password to be displayed, logged, and stored in the browser cache.		
Sink:	nonVendorPasswordUpdate.html:14 null()		
12	<div class="panel-body">		
13	<div class="form-group">		
14	<label>New Password</label> <input		
15	type="password"		
16	class="form-control"		

Category: Cross-Site Scripting: Reflected (1 Issues)

**Explanation:**

Cross-site scripting (XSS) vulnerabilities occur when:

1. Data enters a web application through an untrusted source. In the case of Reflected XSS, the untrusted source is typically a web request, while in the case of Persisted (also known as Stored) XSS it is typically a database or other back-end datastore.
2. The data is included in dynamic content that is sent to a web user without being validated.

The malicious content sent to the web browser often takes the form of a segment of JavaScript, but may also include HTML, Flash or any other type of code that the browser may execute. The variety of attacks based on XSS is almost limitless, but they commonly include transmitting private data like cookies or other session information to the attacker, redirecting the victim to web content controlled by the attacker, or performing other malicious operations on the user's machine under the guise of the vulnerable site.

Example 1: The following PHP code segment reads an employee ID, `eid`, from an HTTP request and displays it to the user.

```
<?php
$id = $_GET['eid'];
...
?>
...
<?php
echo "Employee ID: $id";
?>
```

The code in this example operates correctly if `eid` contains only standard alphanumeric text. If `eid` has a value that includes meta-characters or source code, then the code will be executed by the web browser as it displays the HTTP response.

Initially this might not appear to be much of a vulnerability. After all, why would someone enter a URL that causes malicious code to run on their own computer? The real danger is that an attacker will create the malicious URL, then use e-mail or social engineering tricks to lure victims into visiting a link to the URL. When victims click the link, they unwittingly reflect the malicious content through the vulnerable web application back to their own computers. This mechanism of exploiting vulnerable web applications is known as Reflected XSS.

Example 2: The following PHP code segment queries a database for an employee with a given ID and prints the corresponding employee's name.

```
<?php...
$con = mysql_connect($server,$user,$password);
...
$result = mysql_query("select * from emp where id="+eid);
$row = mysql_fetch_array($result)
echo "Employee name: ", mysql_result($row,0,'name');
...
?>
```

As in Example 1, this code functions correctly when the values of name are well-behaved, but it does nothing to prevent exploits if they are not. Again, this code can appear less dangerous because the value of name is read from a database, whose contents are apparently managed by the application. However, if the value of name originates from user-supplied data, then the database can be a conduit for malicious content. Without proper input validation on all data stored in the database, an attacker can execute malicious commands in the user's web browser. This type of exploit, known as Persistent (or Stored) XSS, is particularly insidious because the indirection caused by the data store makes it more difficult to identify the threat and increases the possibility that the attack will affect multiple users. XSS got its start in this form with web sites that offered a "guestbook" to visitors. Attackers would include JavaScript in their guestbook entries, and all subsequent visitors to the guestbook page would execute the malicious code.

As the examples demonstrate, XSS vulnerabilities are caused by code that includes unvalidated data in an HTTP response. There are three vectors by which an XSS attack can reach a victim:

- As in Example 1, data is read directly from the HTTP request and reflected back in the HTTP response. Reflected XSS exploits occur when an attacker causes a user to supply dangerous content to a vulnerable web application, which is then reflected back to the user and executed by the web browser. The most common mechanism for delivering malicious content is to include it as a parameter in a URL that is posted publicly or e-mailed directly to victims. URLs constructed in this manner constitute the core of many phishing schemes, whereby an attacker convinces victims to visit a URL that refers to a vulnerable site. After the site reflects the attacker's content back to the user, the content is executed and proceeds to transfer private information, such as cookies that may include session information, from the user's machine to the attacker or perform other nefarious activities.
- As in Example 2, the application stores dangerous data in a database or other trusted data store. The dangerous data is subsequently read back into the application and included in dynamic content. Persistent XSS exploits occur when an attacker injects dangerous content into a data store that is later read and included in dynamic content. From an attacker's perspective, the optimal place to inject malicious content is in an area that is displayed to either many users or particularly interesting users. Interesting users typically have elevated privileges in the application or interact with sensitive data that is valuable to the attacker. If one of these users executes malicious content, the attacker may be able to perform privileged operations on behalf of the user or gain access to sensitive data belonging to the user.
- A source outside the application stores dangerous data in a database or other data store, and the dangerous data is subsequently read back into the application as trusted data and included in dynamic content.

Recommendations:

The solution to XSS is to ensure that validation occurs in the correct places and checks for the correct properties.

Since XSS vulnerabilities occur when an application includes malicious data in its output, one logical approach is to validate data immediately before it leaves the application. However, because web applications often have complex and intricate code for generating dynamic content, this method is prone to errors of omission (missing validation). An effective way to mitigate this risk is to also perform input validation for XSS.

Web applications must validate their input to prevent other vulnerabilities, such as SQL injection, so augmenting an application's existing input validation mechanism to include checks for XSS is generally relatively easy. Despite its value, input validation for XSS does not take the place of rigorous output validation. An application may accept input through a shared data store or other trusted source, and that data store may accept input from a source that does not perform adequate input validation. Therefore, the application cannot implicitly rely on the safety of this or any other data. This means the best way to prevent XSS vulnerabilities is to validate everything that enters the application and leaves the application destined for the user.

The most secure approach to validation for XSS is to create a whitelist of safe characters that are allowed to appear in HTTP content and accept input composed exclusively of characters in the approved set. For example, a valid username might only include alpha-numeric characters or a phone number might only include digits 0-9. However, this solution is often infeasible in web applications because many characters that have special meaning to the browser should still be considered valid input once they are encoded, such as a web design bulletin board that must accept HTML fragments from its users.

A more flexible, but less secure approach is known as blacklisting, which selectively rejects or escapes potentially dangerous characters before using the input. In order to form such a list, you first need to understand the set of characters that hold special meaning for web browsers. Although the HTML standard defines what characters have special meaning, many web browsers try to correct common mistakes in HTML and may treat other characters as special in certain contexts, which is why we do not encourage the use of blacklists as a means to prevent XSS. The CERT(R) Coordination Center at the Software Engineering Institute at Carnegie Mellon University provides the following details about special characters in various contexts [1]:

In the content of a block-level element (in the middle of a paragraph of text):

- "<" is special because it introduces a tag.
- "&" is special because it introduces a character entity.
- ">" is special because some browsers treat it as special, on the assumption that the author of the page intended to include an opening "<", but omitted it in error.

The following principles apply to attribute values:

- In attribute values enclosed with double quotes, the double quotes are special because they mark the end of the attribute value.
- In attribute values enclosed with single quote, the single quotes are special because they mark the end of the attribute value.
- In attribute values without any quotes, white-space characters, such as space and tab, are special.
- "&" is special when used with certain attributes, because it introduces a character entity.

In URLs, for example, a search engine might provide a link within the results page that the user can click to re-run the search. This can be implemented by encoding the search query inside the URL, which introduces additional special characters:

- Space, tab, and new line are special because they mark the end of the URL.
- "&" is special because it either introduces a character entity or separates CGI parameters.
- Non-ASCII characters (that is, everything above 128 in the ISO-8859-1 encoding) are not allowed in URLs, so they are considered to be special in this context.
- The "%" symbol must be filtered from input anywhere parameters encoded with HTTP escape sequences are decoded by server-side code. For example, "%" must be filtered if input such as "%68%65%6C%6C%6F" becomes "hello" when it appears on the web page in question.

Within the body of a <SCRIPT> </SCRIPT>:

- Semicolons, parentheses, curly braces, and new line characters should be filtered out in situations where text could be inserted directly into a pre-existing script tag.

Server-side scripts:

- Server-side scripts that convert any exclamation characters (!) in input to double-quote characters (") on output might require additional filtering.

Other possibilities:

- If an attacker submits a request in UTF-7, the special character '<' appears as '+ADw-' and may bypass filtering. If the output is included in a page that does not explicitly specify an encoding format, then some browsers try to intelligently identify the encoding based on the content (in this case, UTF-7).

Once you identify the correct points in an application to perform validation for XSS attacks and what special characters the validation should consider, the next challenge is to identify how your validation handles special characters. If special characters are not considered valid input to the application, then you can reject any input that contains special characters as invalid. A second option in this situation is to remove special characters with filtering. However, filtering has the side effect of changing any visual representation of the filtered content and may be unacceptable in circumstances where the integrity of the input must be preserved for display.

If input containing special characters must be accepted and displayed accurately, validation must encode any special characters to remove their significance. A complete list of ISO 8859-1 encoded values for special characters is provided as part of the official HTML specification [2].

Many application servers attempt to limit an application's exposure to cross-site scripting vulnerabilities by providing implementations for the functions responsible for setting certain specific HTTP response content that perform validation for the characters essential to a cross-site scripting attack. Do not rely on the server running your application to make it secure. When an application is developed there are no guarantees about what application servers it will run on during its lifetime. As standards and known exploits evolve, there are no guarantees that application servers will also stay in sync.

Tips:

1. The HPE Security Fortify Secure Coding Rulepacks warn about SQL Injection and Access Control: Database issues when untrusted data is written to a database and also treat the database as a source of untrusted data, which can lead to XSS vulnerabilities. If the database is a trusted resource in your environment, use custom filters to filter out dataflow issues that include the DATABASE taint flag or originate from database sources. Nonetheless, it is often still a good idea to validate everything read from the database.
2. Even though URL encoding untrusted data protects against many XSS attacks, some browsers (specifically, Internet Explorer 6 and 7 and possibly others) automatically decode content at certain locations within the Document Object Model (DOM) prior to passing it to the JavaScript interpreter. To reflect this danger, the rulepacks no longer treat URL encoding routines as sufficient to protect against cross-site scripting. Data values that are URL encoded and subsequently output will cause Fortify to report Cross-Site Scripting: Poor Validation vulnerabilities.
3. Due to the dynamic nature of PHP, you may see a large number of findings in PHP library files. Consider using a filter file to hide specific findings from view. For instructions on creating a filter file, see Advanced Options in the HPE Security Fortify Static Code Analyzer User Guide.

jsonp.php, line 73 (Cross-Site Scripting: Reflected)

Fortify Priority:	Critical	Folder	Critical
Kingdom:	Input Validation and Representation		
Abstract:	Line 73 of jsonp.php sends unvalidated data to a web browser, which can result in the browser executing malicious code.		
Source:	jsonp.php:68 Read \$_GET['callback']()		
66	// Validate the JSONP to make use it is an okay Javascript function to execute		
67	\$jsonp = preg_match('/^[A-Z_][0-9A-Z_\$]*\$/i', \$_GET['callback']) ?		
68	\$_GET['callback'] :		
69	false;		

```
Sink: jsonp.php:73 builtin_echo()
71     if ( $jsonp ) {
72         echo $jsonp.'('.json_encode(
73             SSP::simple( $_GET, $sql_details, $table, $primaryKey, $columns )
74         ).')';
75     }
```

Category: Path Manipulation (1 Issues)

**Explanation:**

Path manipulation errors occur when the following two conditions are met:

1. An attacker can specify a path used in an operation on the filesystem.
2. By specifying the resource, the attacker gains a capability that would not otherwise be permitted.

For example, the program may give the attacker the ability to overwrite the specified file or run with a configuration controlled by the attacker.

Example 1: The following code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as "../../../tomcat/conf/server.xml", which causes the application to delete one of its own configuration files.

```
$rName = $_GET['reportName'];
$rFile = fopen("/usr/local/apfr/reports/" . rName,"a+");
...
unlink($rFile);
```

Example 2: The following code uses input from a configuration file to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can change the configuration file, they can use the program to read any file on the system that ends with the extension .txt.

```
...
$filename = $CONFIG_TXT['sub'] . ".txt";
$handle = fopen($filename,"r");
$amt = fread($handle, filesize($filename));
echo $amt;
...
```

Recommendations:

The best way to prevent path manipulation is with a level of indirection: create a list of legitimate resource names that a user is allowed to specify, and only allow the user to select from the list. With this approach the input provided by the user is never used directly to specify the resource name.

In some situations this approach is impractical because the set of legitimate resource names is too large or too hard to keep track of. Programmers often resort to blacklisting in these situations. Blacklisting selectively rejects or escapes potentially dangerous characters before using the input. However, any such list of unsafe characters is likely to be incomplete and will almost certainly become out of date. A better approach is to create a whitelist of characters that are allowed to appear in the resource name and accept input composed exclusively of characters in the approved set.

Tips:

1. If the program is performing input validation, satisfy yourself that the validation is correct, and use the HPE Security Fortify Custom Rules Editor to create a cleanse rule for the validation routine.
2. Since implementing a blacklist that is effective on its own is notoriously difficult, if validation logic relies on blacklisting, one should be skeptical. Consider different types of input encoding and different sets of meta-characters that might have special meaning when interpreted by different operating systems, databases, or other resources. Determine whether or not the blacklist can be updated easily, correctly, and completely if these requirements ever change.

3. Due to the dynamic nature of PHP, you may see a large number of findings in PHP library files. Consider using a filter file to hide specific findings from view. For instructions on creating a filter file, see Advanced Options in the HPE Security Fortify Static Code Analyzer User Guide.
